

Database assignment

Task: Complete the list of tasks below.

Task 1:

- Create your cluster with a loadbalancer with port mapping “?:?” via K3d and then create a Mongo deployment yaml file with a service.

```
apiVersion: apps/v1
kind: Deployment
metadata:
  name: mongodb-deployment
spec:
  replicas: 1
  selector:
    matchLabels:
      app: mongodb
  template:
    metadata:
      labels:
        app: mongodb
    spec:
      containers:
        - name: mongodb
          image: mongo
          ports:
            - containerPort: 27017
          env:
            - name: MONGO_INITDB_ROOT_USERNAME
              valueFrom:
                secretKeyRef:
                  name: mongodb-secret
                  key: mongo-root-username
            - name: MONGO_INITDB_ROOT_PASSWORD
              valueFrom:
                secretKeyRef:
```

```
        name: mongodb-secret
        key: mongo-root-password
---
apiVersion: v1
kind: Service
metadata:
  name: mongo-service
spec:
  selector:
    app: mongodb
  ports:
    - protocol: TCP
      port: 27017
      targetPort: 27017
```

- Take note of the container port, root username and password field.

Task 2:

- Now it's time to create a secret yaml file for your username and password
- You will need to open WSL (Windows) or Mac terminal and use this command to encode your string to base64:

```
$echo -n example_username | base64
```

- Run the same command for the password and copy and paste the encoded username and password in a text doc.
- Now enter the base64 encoded string into the username and password field

```
apiVersion: v1
```

```
kind: Secret
metadata:
  name: mongodb-secret
type: Opaque
data:
  mongo-root-username: {base64 encoded string}
  mongo-root-password: {base64 encoded string}
```

Task 3:

- Time to deploy the mongo database but first you must create the secret yaml file with:

```
kubectl apply -f {secret_filename}
```

- Now you can create the deployment

```
kubectl apply -f {deployment_filename}
```

- Take note of what type of service the container is using

Task 4:

- Time to create a config_map file that will allow your application to connect to your database:

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: mongodb-configmap
data:
  database_url: mongo-service
```

- Take note of the database_url
- Next it's time to create the mongo-express application deployment:

```
apiVersion: apps/v1
kind: Deployment
metadata:
  name: mongoexp-deployment
spec:
  replicas: 1
  selector:
    matchLabels:
      app: mongo-express
  template:
    metadata:
      labels:
        app: mongo-express
    spec:
      containers:
        - name: mongo-express
          image: mongo-express
          ports:
            - containerPort: 8081
          env:
            - name: ME_CONFIG_MONGODB_ADMINUSERNAME
              valueFrom:
                secretKeyRef:
                  name: mongodb-secret
                  key: mongo-root-username
            - name: ME_CONFIG_MONGODB_ADMINPASSWORD
              valueFrom:
                secretKeyRef:
                  name: mongodb-secret
                  key: mongo-root-password
            - name: ME_CONFIG_MONGODB_SERVER
              valueFrom:
                configMapKeyRef:
                  name: mongodb-configmap
                  key: database_url
---
apiVersion: v1
kind: Service
metadata:
  name: mongo-exp-service
spec:
  selector:
    app: mongo-express
  type: {you pick the service}
  ports:
    - protocol: TCP
      port: {you pick the port}
      targetPort: {you pick the port}
```

- A few things to take note of:
 - The env section of this file and the mongodb file.
 - The names and keys.
 - You will have to choose the service (nodeport, loadbalancer, ClusterIP), target port and port for the service section.

- First create the configmap with:

```
kubectl apply -f {configmap_filename}
```

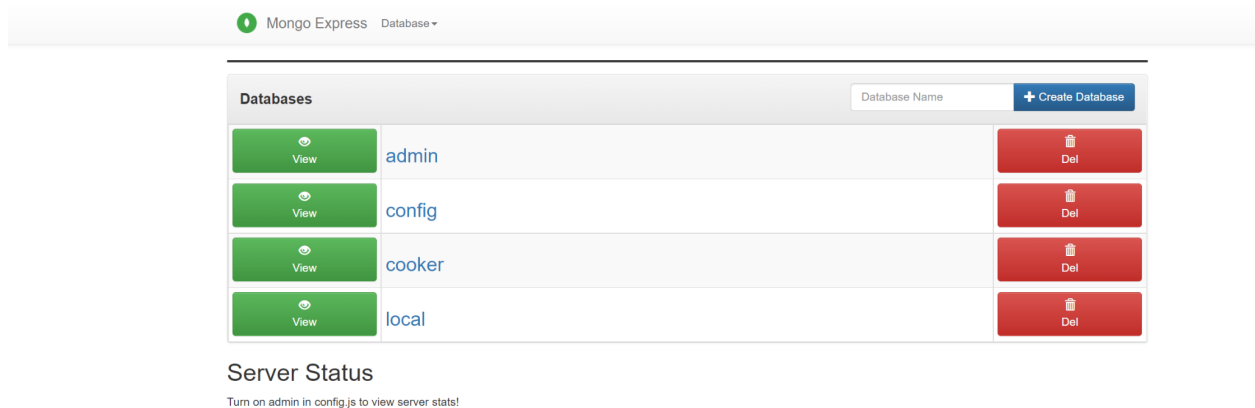

- Now you can create the mongo-express deployment application

Task 5:

- Now access the mongo-express application

Task 6 :

- Add data to the database via the UI to test your database:
 - Create a New database name (you can call it test)
 - Create a new collection (you can call it recipe)

Viewing Database: cooker

Rename Collection

cooker

examples

Rename

- View the recipe collection and click on new document and paste the data set below:

```
{
  title: 'Chicken Soft Tacos',
  calories_per_serving: 205,
  cook_time: 19,
  desc: 'Mexican soft tacos',
  directions: [
    'Put seasoning on chicken breasts',
    'Grill until done',
    'Chop chicken into peices',
  ]
}
```

```
    'Put in totillas'
  ],
  ingredients: [
    {
      name: 'chicken breast',
      quantity: {
        amount: 1,
        unit: 'lbs'
      }
    },
    {
      name: 'taco seasoning',
      quantity: {
        amount: 2,
        unit: 'oz'
      }
    },
    {
      name: 'small flour totillas',
      quantity: {
        amount: 12,
        unit: 'oz'
      }
    }
  ],
  likes: [
    261,
    1,
    415
  ],
  likes_count: 3,
  prep_time: 10,
  rating: [
    4,
    4,
    4,
    4,
    2,
    5,
    3
  ],
  rating_avg: 3.71,
  servings: 5,
```

```
tags: [  
  'mexican',  
  'quick',  
  'easy',  
  'chicken'  
],  
type: 'Dinner'  
}
```

- Once you are successful with uploading the dataset, you are done!!!

Task 7 :

- Create a topology of what you just created.
